Lecture 5, page 1: enzymes
Point 1: enzymes is a key idea that students should be able to explain in their own words.
Point 2: enzymes links closely to how cells stay alive and keep their inside conditions steady.
Point 3: enzymes was first described by scientists using light microscopes and later electron microscopes.
Point 4: enzymes depends on the temperature and the pH of the surroundings inside the organism.
Point 5: enzymes can be measured in the laboratory with simple experiments and careful observation.
Point 6: enzymes often appears in exam questions that ask for a clear definition and an example.
Point 7: enzymes is a key idea that students should be able to explain in their own words.
Point 8: enzymes links closely to how cells stay alive and keep their inside conditions steady.
Point 9: enzymes was first described by scientists using light microscopes and later electron microscopes.
Point 10: enzymes depends on the temperature and the pH of the surroundings inside the organism.
Point 11: enzymes can be measured in the laboratory with simple experiments and careful observation.
Point 12: enzymes often appears in exam questions that ask for a clear definition and an example.
Point 13: enzymes is a key idea that students should be able to explain in their own words.
Point 14: enzymes links closely to how cells stay alive and keep their inside conditions steady.
Point 15: enzymes was first described by scientists using light microscopes and later electron microscopes.
Point 16: enzymes depends on the temperature and the pH of the surroundings inside the organism.
Point 17: enzymes can be measured in the laboratory with simple experiments and careful observation.
Point 18: enzymes often appears in exam questions that ask for a clear definition and an example.
Point 19: enzymes is a key idea that students should be able to explain in their own words.
Point 20: enzymes links closely to how cells stay alive and keep their inside conditions steady.
Point 21: enzymes was first described by scientists using light microscopes and later electron microscopes.
Point 22: enzymes depends on the temperature and the pH of the surroundings inside the organism.
Point 23: enzymes can be measured in the laboratory with simple experiments and careful observation.
Point 24: enzymes often appears in exam questions that ask for a clear definition and an example.
Point 25: enzymes is a key idea that students should be able to explain in their own words.

Lecture 5, page 2: the cell membrane
Point 1: the cell membrane links closely to how cells stay alive and keep their inside conditions steady.
Point 2: the cell membrane was first described by scientists using light microscopes and later electron microscopes.
Point 3: the cell membrane depends on the temperature and the pH of the surroundings inside the organism.
Point 4: the cell membrane can be measured in the laboratory with simple experiments and careful observation.
Point 5: the cell membrane often appears in exam questions that ask for a clear definition and an example.
Point 6: the cell membrane is a key idea that students should be able to explain in their own words.
Point 7: the cell membrane links closely to how cells stay alive and keep their inside conditions steady.
Point 8: the cell membrane was first described by scientists using light microscopes and later electron microscopes.
Point 9: the cell membrane depends on the temperature and the pH of the surroundings inside the organism.
Point 10: the cell membrane can be measured in the laboratory with simple experiments and careful observation.
Point 11: the cell membrane often appears in exam questions that ask for a clear definition and an example.
Point 12: the cell membrane is a key idea that students should be able to explain in their own words.
Point 13: the cell membrane links closely to how cells stay alive and keep their inside conditions steady.
Point 14: the cell membrane was first described by scientists using light microscopes and later electron microscopes.
Point 15: the cell membrane depends on the temperature and the pH of the surroundings inside the organism.
Point 16: the cell membrane can be measured in the laboratory with simple experiments and careful observation.
Point 17: the cell membrane often appears in exam questions that ask for a clear definition and an example.
Point 18: the cell membrane is a key idea that students should be able to explain in their own words.
Point 19: the cell membrane links closely to how cells stay alive and keep their inside conditions steady.
Point 20: the cell membrane was first described by scientists using light microscopes and later electron microscopes.
Point 21: the cell membrane depends on the temperature and the pH of the surroundings inside the organism.
Point 22: the cell membrane can be measured in the laboratory with simple experiments and careful observation.

Lecture 5, page 3: mitochondria
Point 1: mitochondria was first described by scientists using light microscopes and later electron microscopes.
Point 2: mitochondria depends on the temperature and the pH of the surroundings inside the organism.
Point 3: mitochondria can be measured in the laboratory with simple experiments and careful observation.
Point 4: mitochondria often appears in exam questions that ask for a clear definition and an example.
Point 5: mitochondria is a key idea that students should be able to explain in their own words.
Point 6: mitochondria links closely to how cells stay alive and keep their inside conditions steady.
Point 7: mitochondria was first described by scientists using light microscopes and later electron microscopes.
Point 8: mitochondria depends on the temperature and the pH of the surroundings inside the organism.
Point 9: mitochondria can be measured in the laboratory with simple experiments and careful observation.
Point 10: mitochondria often appears in exam questions that ask for a clear definition and an example.
Point 11: mitochondria is a key idea that students should be able to explain in their own words.
Point 12: mitochondria links closely to how cells stay alive and keep their inside conditions steady.
Point 13: mitochondria was first described by scientists using light microscopes and later electron microscopes.
Point 14: mitochondria depends on the temperature and the pH of the surroundings inside the organism.
Point 15: mitochondria can be measured in the laboratory with simple experiments and careful observation.
Point 16: mitochondria often appears in exam questions that ask for a clear definition and an example.
Point 17: mitochondria is a key idea that students should be able to explain in their own words.
Point 18: mitochondria links closely to how cells stay alive and keep their inside conditions steady.
Point 19: mitochondria was first described by scientists using light microscopes and later electron microscopes.
Point 20: mitochondria depends on the temperature and the pH of the surroundings inside the organism.
Point 21: mitochondria can be measured in the laboratory with simple experiments and careful observation.
Point 22: mitochondria often appears in exam questions that ask for a clear definition and an example.
Point 23: mitochondria is a key idea that students should be able to explain in their own words.

Lecture 5, page 4: ribosomes
Point 1: ribosomes depends on the temperature and the pH of the surroundings inside the organism.
Point 2: ribosomes can be measured in the laboratory with simple experiments and careful observation.
Point 3: ribosomes often appears in exam questions that ask for a clear definition and an example.
Point 4: ribosomes is a key idea that students should be able to explain in their own words.
Point 5: ribosomes links closely to how cells stay alive and keep their inside conditions steady.
Point 6: ribosomes was first described by scientists using light microscopes and later electron microscopes.
Point 7: ribosomes depends on the temperature and the pH of the surroundings inside the organism.
Point 8: ribosomes can be measured in the laboratory with simple experiments and careful observation.
Point 9: ribosomes often appears in exam questions that ask for a clear definition and an example.
Point 10: ribosomes is a key idea that students should be able to explain in their own words.
Point 11: ribosomes links closely to how cells stay alive and keep their inside conditions steady.
Point 12: ribosomes was first described by scientists using light microscopes and later electron microscopes.
Point 13: ribosomes depends on the temperature and the pH of the surroundings inside the organism.
Point 14: ribosomes can be measured in the laboratory with simple experiments and careful observation.
Point 15: ribosomes often appears in exam questions that ask for a clear definition and an example.
Point 16: ribosomes is a key idea that students should be able to explain in their own words.
Point 17: ribosomes links closely to how cells stay alive and keep their inside conditions steady.
Point 18: ribosomes was first described by scientists using light microscopes and later electron microscopes.
Point 19: ribosomes depends on the temperature and the pH of the surroundings inside the organism.
Point 20: ribosomes can be measured in the laboratory with simple experiments and careful observation.
Point 21: ribosomes often appears in exam questions that ask for a clear definition and an example.
Point 22: ribosomes is a key idea that students should be able to explain in their own words.
Point 23: ribosomes links closely to how cells stay alive and keep their inside conditions steady.
Point 24: ribosomes was first described by scientists using light microscopes and later electron microscopes.

Lecture 5, page 5: the nucleus
Point 1: the nucleus can be measured in the laboratory with simple experiments and careful observation.
Point 2: the nucleus often appears in exam questions that ask for a clear definition and an example.
Point 3: the nucleus is a key idea that students should be able to explain in their own words.
Point 4: the nucleus links closely to how cells stay alive and keep their inside conditions steady.
Point 5: the nucleus was first described by scientists using light microscopes and later electron microscopes.
Point 6: the nucleus depends on the temperature and the pH of the surroundings inside the organism.
Point 7: the nucleus can be measured in the laboratory with simple experiments and careful observation.
Point 8: the nucleus often appears in exam questions that ask for a clear definition and an example.
Point 9: the nucleus is a key idea that students should be able to explain in their own words.
Point 10: the nucleus links closely to how cells stay alive and keep their inside conditions steady.
Point 11: the nucleus was first described by scientists using light microscopes and later electron microscopes.
Point 12: the nucleus depends on the temperature and the pH of the surroundings inside the organism.
Point 13: the nucleus can be measured in the laboratory with simple experiments and careful observation.
Point 14: the nucleus often appears in exam questions that ask for a clear definition and an example.
Point 15: the nucleus is a key idea that students should be able to explain in their own words.
Point 16: the nucleus links closely to how cells stay alive and keep their inside conditions steady.
Point 17: the nucleus was first described by scientists using light microscopes and later electron microscopes.
Point 18: the nucleus depends on the temperature and the pH of the surroundings inside the organism.
Point 19: the nucleus can be measured in the laboratory with simple experiments and careful observation.
Point 20: the nucleus often appears in exam questions that ask for a clear definition and an example.
Point 21: the nucleus is a key idea that students should be able to explain in their own words.
Point 22: the nucleus links closely to how cells stay alive and keep their inside conditions steady.
Point 23: the nucleus was first described by scientists using light microscopes and later electron microscopes.
Point 24: the nucleus depends on the temperature and the pH of the surroundings inside the organism.

Lecture 5, page 6: chloroplasts
Point 1: chloroplasts often appears in exam questions that ask for a clear definition and an example.
Point 2: chloroplasts is a key idea that students should be able to explain in their own words.
Point 3: chloroplasts links closely to how cells stay alive and keep their inside conditions steady.
Point 4: chloroplasts was first described by scientists using light microscopes and later electron microscopes.
Point 5: chloroplasts depends on the temperature and the pH of the surroundings inside the organism.
Point 6: chloroplasts can be measured in the laboratory with simple experiments and careful observation.
Point 7: chloroplasts often appears in exam questions that ask for a clear definition and an example.
Point 8: chloroplasts is a key idea that students should be able to explain in their own words.
Point 9: chloroplasts links closely to how cells stay alive and keep their inside conditions steady.
Point 10: chloroplasts was first described by scientists using light microscopes and later electron microscopes.
Point 11: chloroplasts depends on the temperature and the pH of the surroundings inside the organism.
Point 12: chloroplasts can be measured in the laboratory with simple experiments and careful observation.
Point 13: chloroplasts often appears in exam questions that ask for a clear definition and an example.
Point 14: chloroplasts is a key idea that students should be able to explain in their own words.
Point 15: chloroplasts links closely to how cells stay alive and keep their inside conditions steady.
Point 16: chloroplasts was first described by scientists using light microscopes and later electron microscopes.
Point 17: chloroplasts depends on the temperature and the pH of the surroundings inside the organism.
Point 18: chloroplasts can be measured in the laboratory with simple experiments and careful observation.
Point 19: chloroplasts often appears in exam questions that ask for a clear definition and an example.
Point 20: chloroplasts is a key idea that students should be able to explain in their own words.
Point 21: chloroplasts links closely to how cells stay alive and keep their inside conditions steady.
Point 22: chloroplasts was first described by scientists using light microscopes and later electron microscopes.
Point 23: chloroplasts depends on the temperature and the pH of the surroundings inside the organism.

Lecture 5, page 7: osmosis
Point 1: osmosis is a key idea that students should be able to explain in their own words.
Point 2: osmosis links closely to how cells stay alive and keep their inside conditions steady.
Point 3: osmosis was first described by scientists using light microscopes and later electron microscopes.
Point 4: osmosis depends on the temperature and the pH of the surroundings inside the organism.
Point 5: osmosis can be measured in the laboratory with simple experiments and careful observation.
Point 6: osmosis often appears in exam questions that ask for a clear definition and an example.
Point 7: osmosis is a key idea that students should be able to explain in their own words.
Point 8: osmosis links closely to how cells stay alive and keep their inside conditions steady.
Point 9: osmosis was first described by scientists using light microscopes and later electron microscopes.
Point 10: osmosis depends on the temperature and the pH of the surroundings inside the organism.
Point 11: osmosis can be measured in the laboratory with simple experiments and careful observation.
Point 12: osmosis often appears in exam questions that ask for a clear definition and an example.
Point 13: osmosis is a key idea that students should be able to explain in their own words.
Point 14: osmosis links closely to how cells stay alive and keep their inside conditions steady.
Point 15: osmosis was first described by scientists using light microscopes and later electron microscopes.
Point 16: osmosis depends on the temperature and the pH of the surroundings inside the organism.
Point 17: osmosis can be measured in the laboratory with simple experiments and careful observation.
Point 18: osmosis often appears in exam questions that ask for a clear definition and an example.
Point 19: osmosis is a key idea that students should be able to explain in their own words.
Point 20: osmosis links closely to how cells stay alive and keep their inside conditions steady.
Point 21: osmosis was first described by scientists using light microscopes and later electron microscopes.
Point 22: osmosis depends on the temperature and the pH of the surroundings inside the organism.
Point 23: osmosis can be measured in the laboratory with simple experiments and careful observation.
Point 24: osmosis often appears in exam questions that ask for a clear definition and an example.
Point 25: osmosis is a key idea that students should be able to explain in their own words.

Lecture 5, page 8: diffusion
Point 1: diffusion links closely to how cells stay alive and keep their inside conditions steady.
Point 2: diffusion was first described by scientists using light microscopes and later electron microscopes.
Point 3: diffusion depends on the temperature and the pH of the surroundings inside the organism.
Point 4: diffusion can be measured in the laboratory with simple experiments and careful observation.
Point 5: diffusion often appears in exam questions that ask for a clear definition and an example.
Point 6: diffusion is a key idea that students should be able to explain in their own words.
Point 7: diffusion links closely to how cells stay alive and keep their inside conditions steady.
Point 8: diffusion was first described by scientists using light microscopes and later electron microscopes.
Point 9: diffusion depends on the temperature and the pH of the surroundings inside the organism.
Point 10: diffusion can be measured in the laboratory with simple experiments and careful observation.
Point 11: diffusion often appears in exam questions that ask for a clear definition and an example.
Point 12: diffusion is a key idea that students should be able to explain in their own words.
Point 13: diffusion links closely to how cells stay alive and keep their inside conditions steady.
Point 14: diffusion was first described by scientists using light microscopes and later electron microscopes.
Point 15: diffusion depends on the temperature and the pH of the surroundings inside the organism.
Point 16: diffusion can be measured in the laboratory with simple experiments and careful observation.
Point 17: diffusion often appears in exam questions that ask for a clear definition and an example.
Point 18: diffusion is a key idea that students should be able to explain in their own words.
Point 19: diffusion links closely to how cells stay alive and keep their inside conditions steady.
Point 20: diffusion was first described by scientists using light microscopes and later electron microscopes.
Point 21: diffusion depends on the temperature and the pH of the surroundings inside the organism.
Point 22: diffusion can be measured in the laboratory with simple experiments and careful observation.
Point 23: diffusion often appears in exam questions that ask for a clear definition and an example.
Point 24: diffusion is a key idea that students should be able to explain in their own words.

Lecture 5, page 9: active transport
Point 1: active transport was first described by scientists using light microscopes and later electron microscopes.
Point 2: active transport depends on the temperature and the pH of the surroundings inside the organism.
Point 3: active transport can be measured in the laboratory with simple experiments and careful observation.
Point 4: active transport often appears in exam questions that ask for a clear definition and an example.
Point 5: active transport is a key idea that students should be able to explain in their own words.
Point 6: active transport links closely to how cells stay alive and keep their inside conditions steady.
Point 7: active transport was first described by scientists using light microscopes and later electron microscopes.
Point 8: active transport depends on the temperature and the pH of the surroundings inside the organism.
Point 9: active transport can be measured in the laboratory with simple experiments and careful observation.
Point 10: active transport often appears in exam questions that ask for a clear definition and an example.
Point 11: active transport is a key idea that students should be able to explain in their own words.
Point 12: active transport links closely to how cells stay alive and keep their inside conditions steady.
Point 13: active transport was first described by scientists using light microscopes and later electron microscopes.
Point 14: active transport depends on the temperature and the pH of the surroundings inside the organism.
Point 15: active transport can be measured in the laboratory with simple experiments and careful observation.
Point 16: active transport often appears in exam questions that ask for a clear definition and an example.
Point 17: active transport is a key idea that students should be able to explain in their own words.
Point 18: active transport links closely to how cells stay alive and keep their inside conditions steady.
Point 19: active transport was first described by scientists using light microscopes and later electron microscopes.
Point 20: active transport depends on the temperature and the pH of the surroundings inside the organism.
Point 21: active transport can be measured in the laboratory with simple experiments and careful observation.
Point 22: active transport often appears in exam questions that ask for a clear definition and an example.

Lecture 5, page 10: DNA replication

Point 1: DNA replication depends on the temperature and the pH of the surroundings inside the organism.

Point 2: DNA replication can be measured in the laboratory with simple experiments and careful observation.

Point 3: DNA replication often appears in exam questions that ask for a clear definition and an example.

Point 4: DNA replication is a key idea that students should be able to explain in their own words.

Point 5: DNA replication links closely to how cells stay alive and keep their inside conditions steady.

Point 6: DNA replication was first described by scientists using light microscopes and later electron microscopes.

Point 7: DNA replication depends on the temperature and the pH of the surroundings inside the organism.

Point 8: DNA replication can be measured in the laboratory with simple experiments and careful observation.

Point 9: DNA replication often appears in exam questions that ask for a clear definition and an example.

Point 10: DNA replication is a key idea that students should be able to explain in their own words.

Point 11: DNA replication links closely to how cells stay alive and keep their inside conditions steady.

Point 12: DNA replication was first described by scientists using light microscopes and later electron microscopes.

Point 13: DNA replication depends on the temperature and the pH of the surroundings inside the organism.

Point 14: DNA replication can be measured in the laboratory with simple experiments and careful observation.

Point 15: DNA replication often appears in exam questions that ask for a clear definition and an example.

Point 16: DNA replication is a key idea that students should be able to explain in their own words.

Point 17: DNA replication links closely to how cells stay alive and keep their inside conditions steady.

Point 18: DNA replication was first described by scientists using light microscopes and later electron microscopes.

Point 19: DNA replication depends on the temperature and the pH of the surroundings inside the organism.

Point 20: DNA replication can be measured in the laboratory with simple experiments and careful observation.

Point 21: DNA replication often appears in exam questions that ask for a clear definition and an example.

Point 22: DNA replication is a key idea that students should be able to explain in their own words.

Point 23: DNA replication links closely to how cells stay alive and keep their inside conditions steady.

Lecture 5, page 11: protein synthesis
Point 1: protein synthesis can be measured in the laboratory with simple experiments and careful observation.
Point 2: protein synthesis often appears in exam questions that ask for a clear definition and an example.
Point 3: protein synthesis is a key idea that students should be able to explain in their own words.
Point 4: protein synthesis links closely to how cells stay alive and keep their inside conditions steady.
Point 5: protein synthesis was first described by scientists using light microscopes and later electron microscopes.
Point 6: protein synthesis depends on the temperature and the pH of the surroundings inside the organism.
Point 7: protein synthesis can be measured in the laboratory with simple experiments and careful observation.
Point 8: protein synthesis often appears in exam questions that ask for a clear definition and an example.
Point 9: protein synthesis is a key idea that students should be able to explain in their own words.
Point 10: protein synthesis links closely to how cells stay alive and keep their inside conditions steady.
Point 11: protein synthesis was first described by scientists using light microscopes and later electron microscopes.
Point 12: protein synthesis depends on the temperature and the pH of the surroundings inside the organism.
Point 13: protein synthesis can be measured in the laboratory with simple experiments and careful observation.
Point 14: protein synthesis often appears in exam questions that ask for a clear definition and an example.
Point 15: protein synthesis is a key idea that students should be able to explain in their own words.
Point 16: protein synthesis links closely to how cells stay alive and keep their inside conditions steady.
Point 17: protein synthesis was first described by scientists using light microscopes and later electron microscopes.
Point 18: protein synthesis depends on the temperature and the pH of the surroundings inside the organism.
Point 19: protein synthesis can be measured in the laboratory with simple experiments and careful observation.
Point 20: protein synthesis often appears in exam questions that ask for a clear definition and an example.
Point 21: protein synthesis is a key idea that students should be able to explain in their own words.
Point 22: protein synthesis links closely to how cells stay alive and keep their inside conditions steady.

Lecture 5, page 12: cell division
Point 1: cell division often appears in exam questions that ask for a clear definition and an example.
Point 2: cell division is a key idea that students should be able to explain in their own words.
Point 3: cell division links closely to how cells stay alive and keep their inside conditions steady.
Point 4: cell division was first described by scientists using light microscopes and later electron microscopes.
Point 5: cell division depends on the temperature and the pH of the surroundings inside the organism.
Point 6: cell division can be measured in the laboratory with simple experiments and careful observation.
Point 7: cell division often appears in exam questions that ask for a clear definition and an example.
Point 8: cell division is a key idea that students should be able to explain in their own words.
Point 9: cell division links closely to how cells stay alive and keep their inside conditions steady.
Point 10: cell division was first described by scientists using light microscopes and later electron microscopes.
Point 11: cell division depends on the temperature and the pH of the surroundings inside the organism.
Point 12: cell division can be measured in the laboratory with simple experiments and careful observation.
Point 13: cell division often appears in exam questions that ask for a clear definition and an example.
Point 14: cell division is a key idea that students should be able to explain in their own words.
Point 15: cell division links closely to how cells stay alive and keep their inside conditions steady.
Point 16: cell division was first described by scientists using light microscopes and later electron microscopes.
Point 17: cell division depends on the temperature and the pH of the surroundings inside the organism.
Point 18: cell division can be measured in the laboratory with simple experiments and careful observation.
Point 19: cell division often appears in exam questions that ask for a clear definition and an example.
Point 20: cell division is a key idea that students should be able to explain in their own words.
Point 21: cell division links closely to how cells stay alive and keep their inside conditions steady.
Point 22: cell division was first described by scientists using light microscopes and later electron microscopes.
Point 23: cell division depends on the temperature and the pH of the surroundings inside the organism.
